Tools:
We cleaned and analyzed the survey in Python with pandas (matplotlib for charts) in Jupyter notebooks. We planned the notebooks ourselves and used Claude to write the code, then ran each step and checked its output against the data. We also used Claude to check our work against the case brief and to edit the memo, and to help script, edit audio and the demo video.
Representative prompts:

- "According to the case brief and the analysis, does the analysis actually follow it?"
- "Merge them into one file and make it strongly centered around the key points within the memo."

How we refined the output:

- Requiring every question to be answered left only 135 of 1,299 responses, because one question was missing from most form versions. We changed the rule to keep rows with all six before/after answers and to analyze other questions only where they were answered.
- We merged the separate cleaning and analysis notebooks into one notebook that runs from the raw export to every number in the memo.

AI errors and limitations:

1. The analysis notebook failed to run: it looked for the cleaned file in the wrong folder. Merging the notebooks fixed it.
2. An early table showed Spanish speakers less confident after training (78% vs 85%). Most of that gap came from answers that likely read the scale backwards; after flagging them it was about 83% vs 86%.
3. A draft memo figure on question-style comments could not be traced to any code, so we rebuilt the count in the notebook.
4. The code contained presenter names; we moved them to a private file so they are not shared.

What we verified ourselves:

- A mislabeled column ("TRIM(")) is the completion time: completion minus start equals time taken on every row.
- We reproduced the earlier 135-row result to confirm why it was so small.
- We read the comments marked as Spanish and samples of each theme to check the coding.
- Every chart is shown beside the table it comes from; the memo quotes the tables, since AI-made charts can be wrong.
