SUBJECT: Team 5 Process Memo

Key Findings

Spanish speakers are undercounted. Only 19 respondents (1.5%) used the Spanish survey, but 66 (5.1%) wrote their comments in Spanish, and 53 of those used the English form. Counting either group, 72 respondents (5.6%) are Spanish speakers. This points to a survey-access gap, such as a default English link or no visible language option. Spanish-writing respondents gained about as much from the training as everyone else, so the data does not show that the training worked less well for them.

People leave with unanswered questions. Of the 647 respondents who answered, "How can we improve this training?" 222 (34%) asked a question instead of making a suggestion. We grouped the questions by theme. The most common were how many people use 988 and whether it works (45), what happens when you call (21), and whether you can contact 988 if you're not in crisis or are worried about someone else (18). The training itself could answer all three, so we recommend adding a short Q&A segment and tracking the share of question-style comments each quarter to see if it helps.

Methodology

The raw survey export (1,299 responses) was cleaned in a documented notebook, with Claude assisting to generate code to filter and us checking for accuracy, after each func. In doing so, we:

- Tidied the data by fixing column names, spelling variants, and hidden characters (such as invisible extra spaces), and grouped counties into six standard values.
- Converted agree/disagree answers to a 1-to-5 scale. We merged two spellings of "neither agree nor disagree" (237 responses) and recoded two non-standard answers, "Very agree" and "Satisfied," to "Strongly agree" and "Agree" (24 responses, marked for review).
- Identified Spanish speakers from either the survey language or the language of their written comments, which caught 53 Spanish comments on the English survey.

Recommendations

Automate the review. Today, checking whether the training works means someone sorts through survey results by hand every time. We recommend setting this up once so it runs automatically. When new survey results arrive, staff load them into Python, which shows how much participants' confidence grew after the training. It reports this for each skill (spotting a crisis, explaining what 988 is, and knowing when to use it) and for groups such as students, parents, and community members, and it shows how many people answered, so staff know how much to trust each number.

Many Spanish speakers are filling out the survey in English, which suggests the Spanish option is hard to find, not that few Spanish speakers attend. We recommend letting people choose their language at the start of the survey, not limited to just Spanish. They should also record which language each training was given in, so EveryMind can tell whether a problem comes from the survey or the training itself. Using census data on languages spoken at home, each county decides which languages to add beyond Spanish, so the choice is based on real community needs.

Give questions their own place, and use them to check what people learned. Leave time for questions in every session, and explain what actually happens when someone contacts 988. Add an optional survey question, "What questions do you still have about 988?", so questions don't crowd out suggestions and can be answered in a follow-up FAQ reviewed by 988 staff. Then turn the three most common questions into short quiz questions (for example, "Can you contact 988 if you're worried about someone else?"). This shows what people learned, not just how confident they feel.

How EveryMind will know it worked: the three most common questions appear in fewer than 7% of comments across both boxes (13% of improvement comments now), and quiz results improve from the first quarter's baseline toward at least 80% correct.

Implementation

One staff member would own the process each quarter, using Python, Tableau, and the survey's Excel export:

1. **Export.** Save the quarter's Excel export and load it into Python.
2. **Automatic check.** Python cleans the data consistently and flags issues such as missing questions, unusual labels, or suspicious responses.
3. **Update.** Python refreshes the Tableau dashboard with new data from the quarter, with an option to go back to previous quarters to compare.
4. **Team review.** The staff member reviews the dashboard with the team and discusses changes or improvements to be made.

This takes about one to two hours per quarter. Because the same steps run each time, results stay comparable across quarters, and the cleaning notebook documents every decision so a new staff member can pick it up.

Limitations

- With a quarterly run, an issue such as a question left off the form could go unnoticed for up to three months. Staff can check the survey form whenever it changes, or glance at responses after the first few sessions of each quarter.
- Results reflect one main group. About 83% of respondents are students, and about 72% are from Anne Arundel County, so the overall results mostly describe Anne Arundel students.
- Language is estimated. The survey does not ask what language people speak, so we identified Spanish speakers from the survey language or Spanish comments. The count (72, about 5.6%) is approximate and likely too low, and answers from Spanish speakers who used the English survey may be less accurate.
